If the unknown is below the line, first bring it UP

✗ Wrong way: we get 1/x, not x

1 Equation (we want x). $5 = \frac{20}{x}$

2 We divide both sides by 20 (the 20 "goes dividing"). $\frac{5}{20} = \frac{1}{x}$

? x is still **below** the line: we have **1/x**, not x. It is **not** isolated! $\frac{1}{x} = 0{,}25$

✓ Right way: bring x up first

1 Equation (we want x). $5 = \frac{20}{x}$

2 x is **dividing**: it goes to the other side **multiplying** (now it is up). $5 \cdot x = 20$

3 5 is **multiplying** x: it goes to the other side **dividing**. $x = \frac{20}{5} = 4$

When the quantity we want is **in the denominator**, the **first step** is always to **multiply both sides by it** (it "goes up multiplying"). Then we isolate it as usual.
