Displacement (Δx) and time interval (Δt)

x = **position**: where the object is, measured from the origin.
It is a **length**, so it is measured in **metres (m)**.

$$\Delta x = x_f - x_i$$

displacement: final position minus initial position
(Δ, "delta", means "change in")

$$\Delta t = t_f - t_i$$

time interval: final time minus initial time
7 s − 2 s = **5 s**
